

On the surface, *Monotone Satisfiability with Few True Variables* (which we'll abbreviate *Monotone Satisfiability with Few True Variables*) is written in the language of the Satisfiability problem. But at a technical level, it's not so closely connected to *SAT*; after all no variables appear negated, and what makes it hard is the constraint that only a few variables can be set to true.

Really, what's going on is that one has to choose a small number of variables, in such a way that each clause contains one of the chosen variables. Phrased this way, it resembles a type of covering problem.

We choose *Vertex Cover* as the problem  $X$ , and show  $\text{Vertex Cover} \leq_P \text{Monotone Satisfiability with Few True Variables}$ . Suppose we are given a graph  $G = (V, E)$  and a number  $k$ ; we want to decide whether there is a vertex cover in  $G$  of size at most  $k$ . We create an equivalent instance of *Monotone Satisfiability with Few True Variables* as follows. We have a variable  $x_i$  for each vertex  $v_i$ . For each edge  $e_j = (v_a, v_b)$ , we create the clause  $C_j = (x_a \vee x_b)$ . This is the full instance: we have clauses  $C_1, C_2, \dots, C_m$ , one for each edge of  $G$ , and we want to know if they can all be satisfied by setting at most  $k$  variables to 1.

We claim that the answer to the *Vertex Cover* instance is “yes” if and only if the answer to the *Monotone Satisfiability with Few True Variables* instance is “yes.” For suppose there is a vertex cover  $S$  in  $G$  of size at most  $k$ , and consider the effect of setting the corresponding variables to 1 (and all other variables to 0). Since each edge is covered by a member of  $S$ , each clause contains at least one variable set to 1, and so all clauses are satisfied. Conversely, suppose there is a way to satisfy all clauses by setting a subset  $X$  of at most  $k$  variables to 1. Then if we consider the corresponding vertices in  $G$ , each edge must have at least one end equal to one of these vertices — since the clause corresponding to this edge contains a variable in  $X$ . Thus the nodes corresponding to the variables in  $X$  form a vertex cover of size at most  $k$ .
